## Aim:

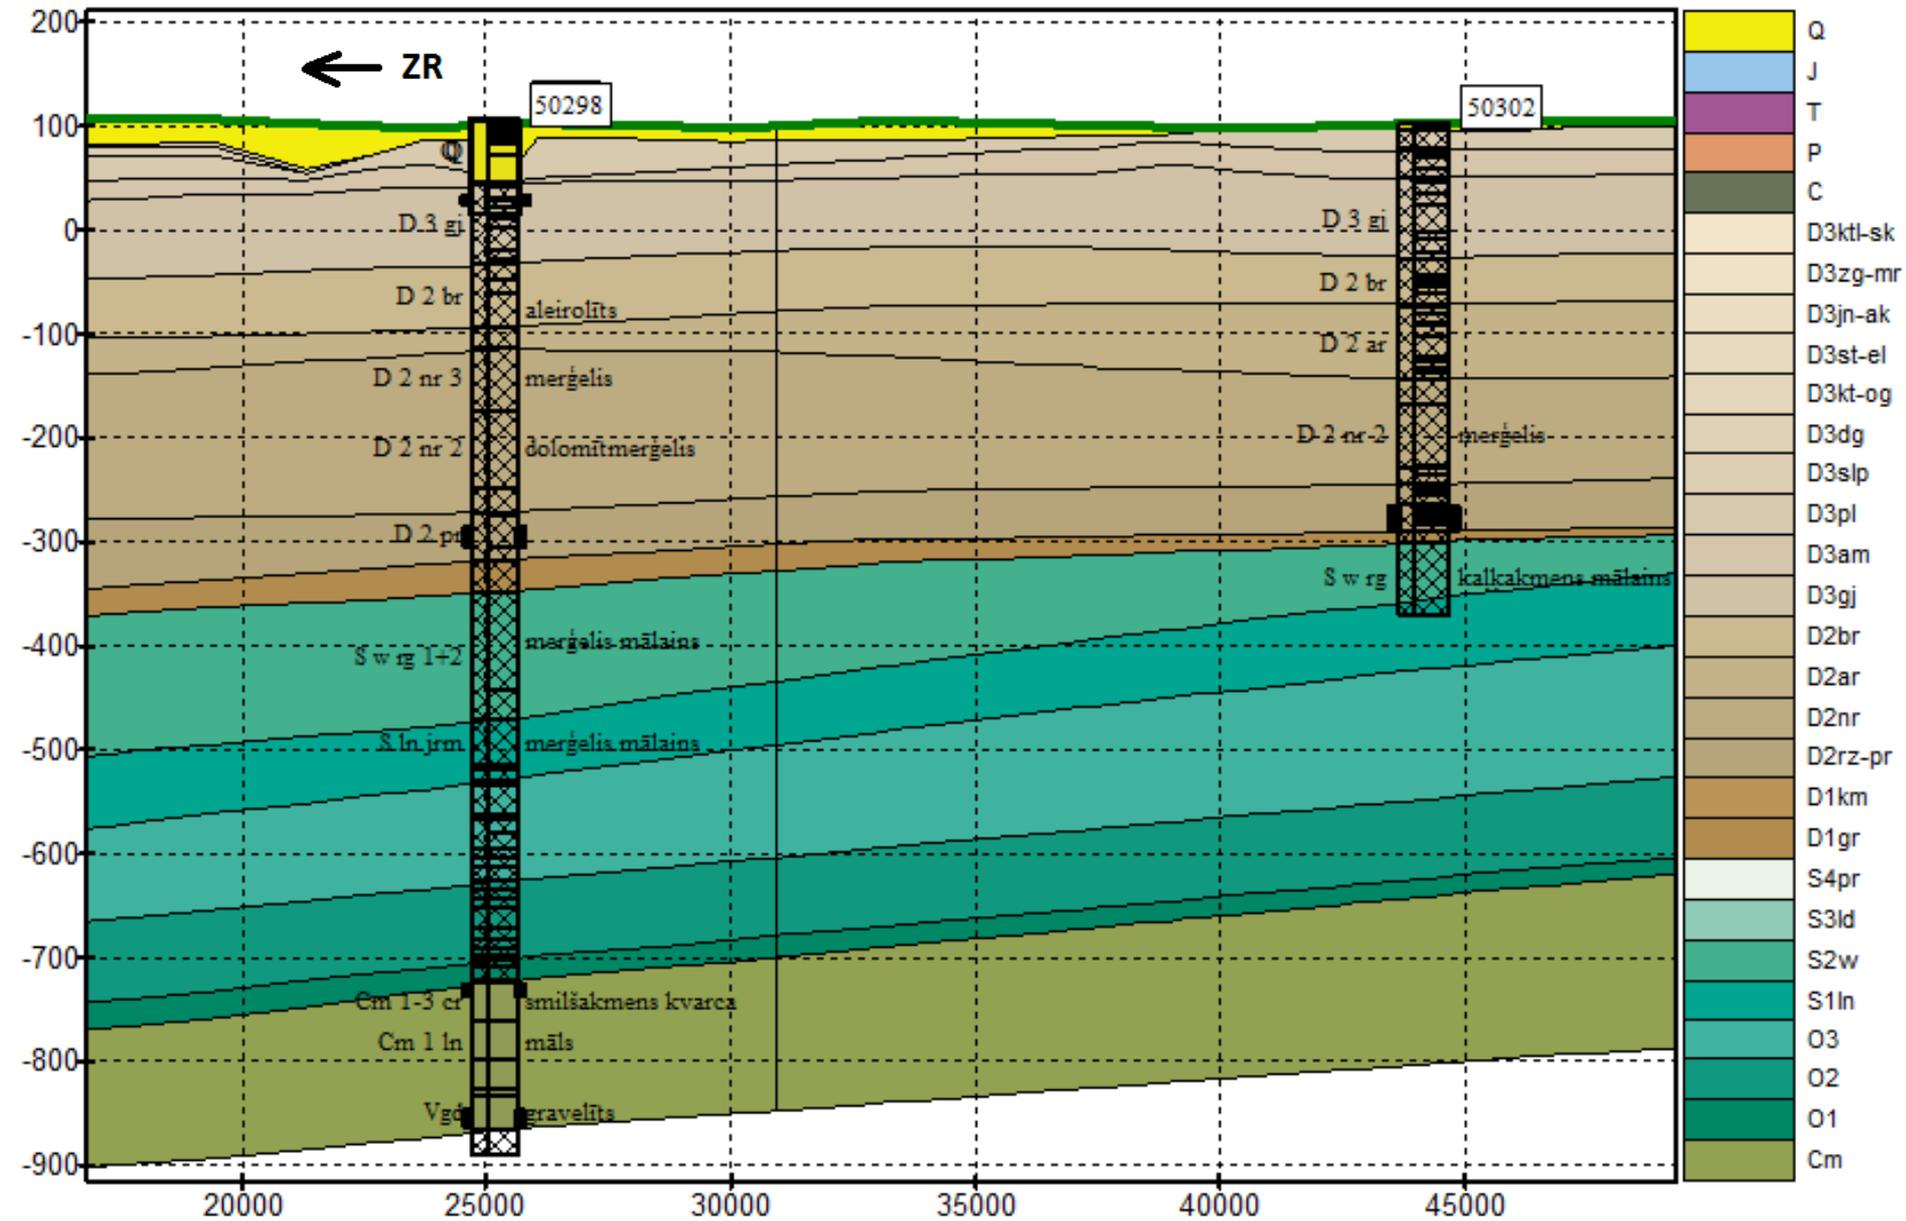

- The aim of this study is to find characteristic hydraulic conductivity values for each aquifer based on aquifer grain size distribution and lithology on the one hand and pumping test results on the other;

## Main tasks:

- Obtaining of basically necessary data – geological information - grain size analysis results and hydrogeological data – pumping tests results (hydraulic conductivity);
- Correlation between grain size distribution and hydraulic conductivity values and estimation of characteristic values of hydraulic conductivity for each aquifer;
- Calculation of hydraulic conductivity from grain size analysis data;

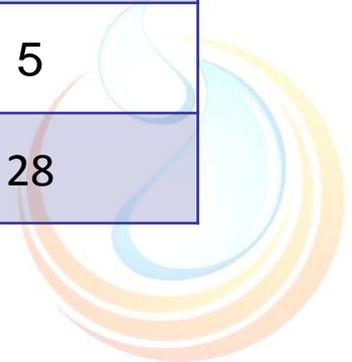

# Geology

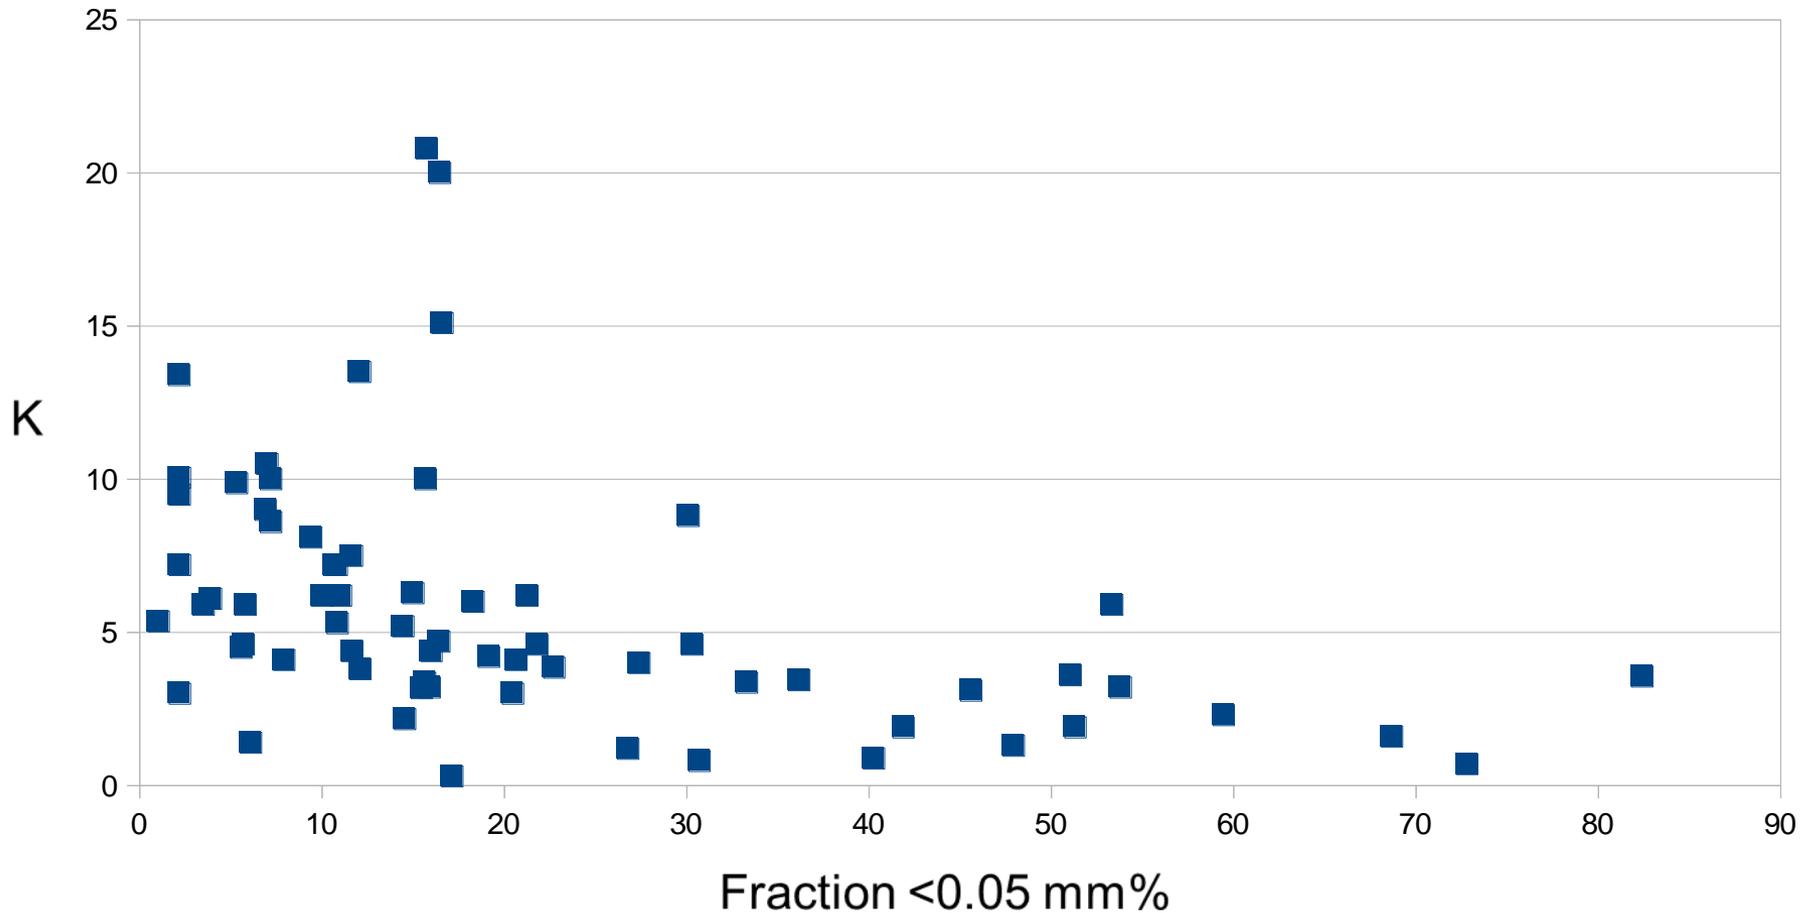

# Data

Aquifer	K (Number of wells)	Grain size analysis (Number of wells)	K + grain size (Number of wells)
D <sub>3am</sub>	66	82	7
D <sub>3gj</sub>	152	124	22
D <sub>2br</sub>	89	104	17
D <sub>2ar</sub>	95	96	14
D <sub>2rz-pr</sub>	46	39	5
Cm	52	94	28

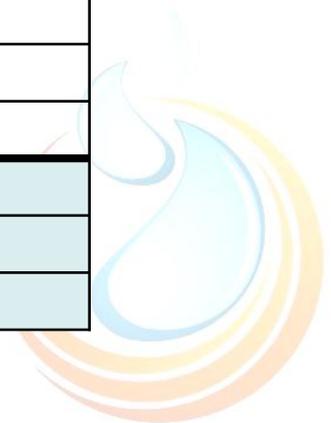

# Common correlation between hydraulic conductivity (K) and grain size distribution in Devonian aquifers

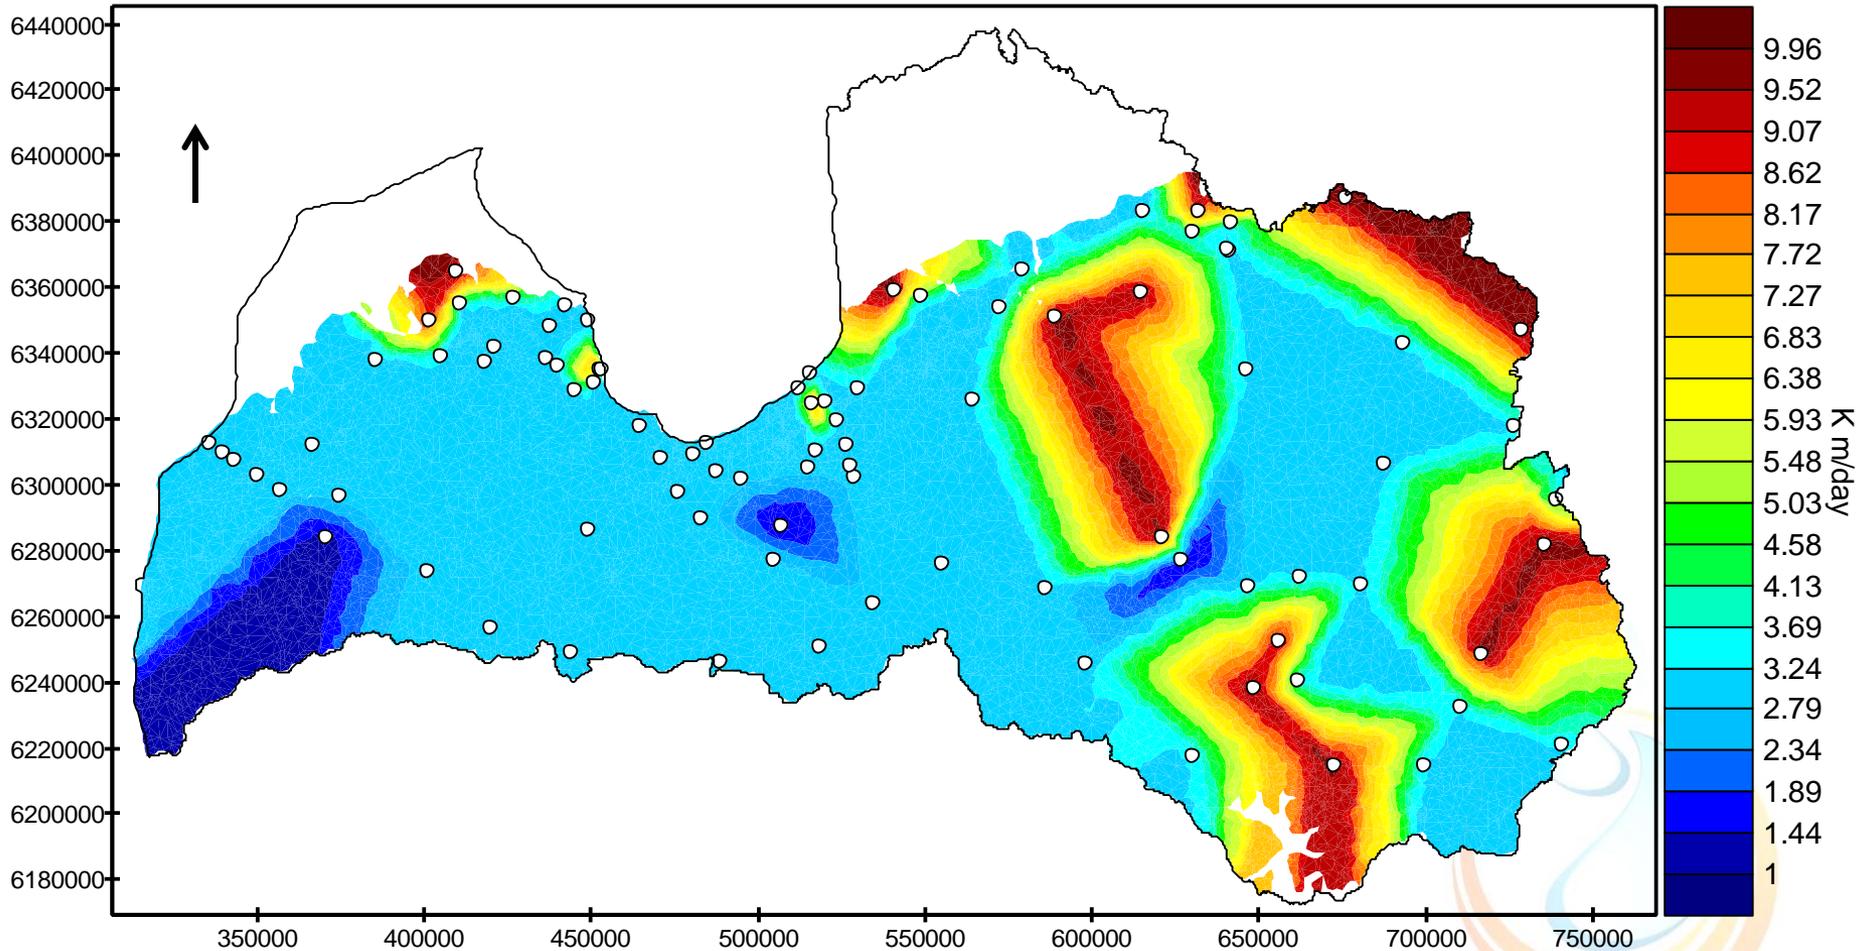

## Common correlation between hydraulic conductivity (K) and grain size distribution in Devonian

# Visualization of correlation between grain size distribution and hydraulic conductivity in Gauja aquifer

# Hydraulic conductivity calculation from grain size distribution

- Effective diameter ( $d_{10}$ ) calculation;
- Hydraulic conductivity calculation

$$K = Cd_e^2(0,7 + 0,03t)$$

Hazen formula:

$K$  – hydraulic conductivity (m/day)

$C$  – empirical coefficient - varies from 400 (clays) – 1200 (well sorted sands) (Fetter, 2001),

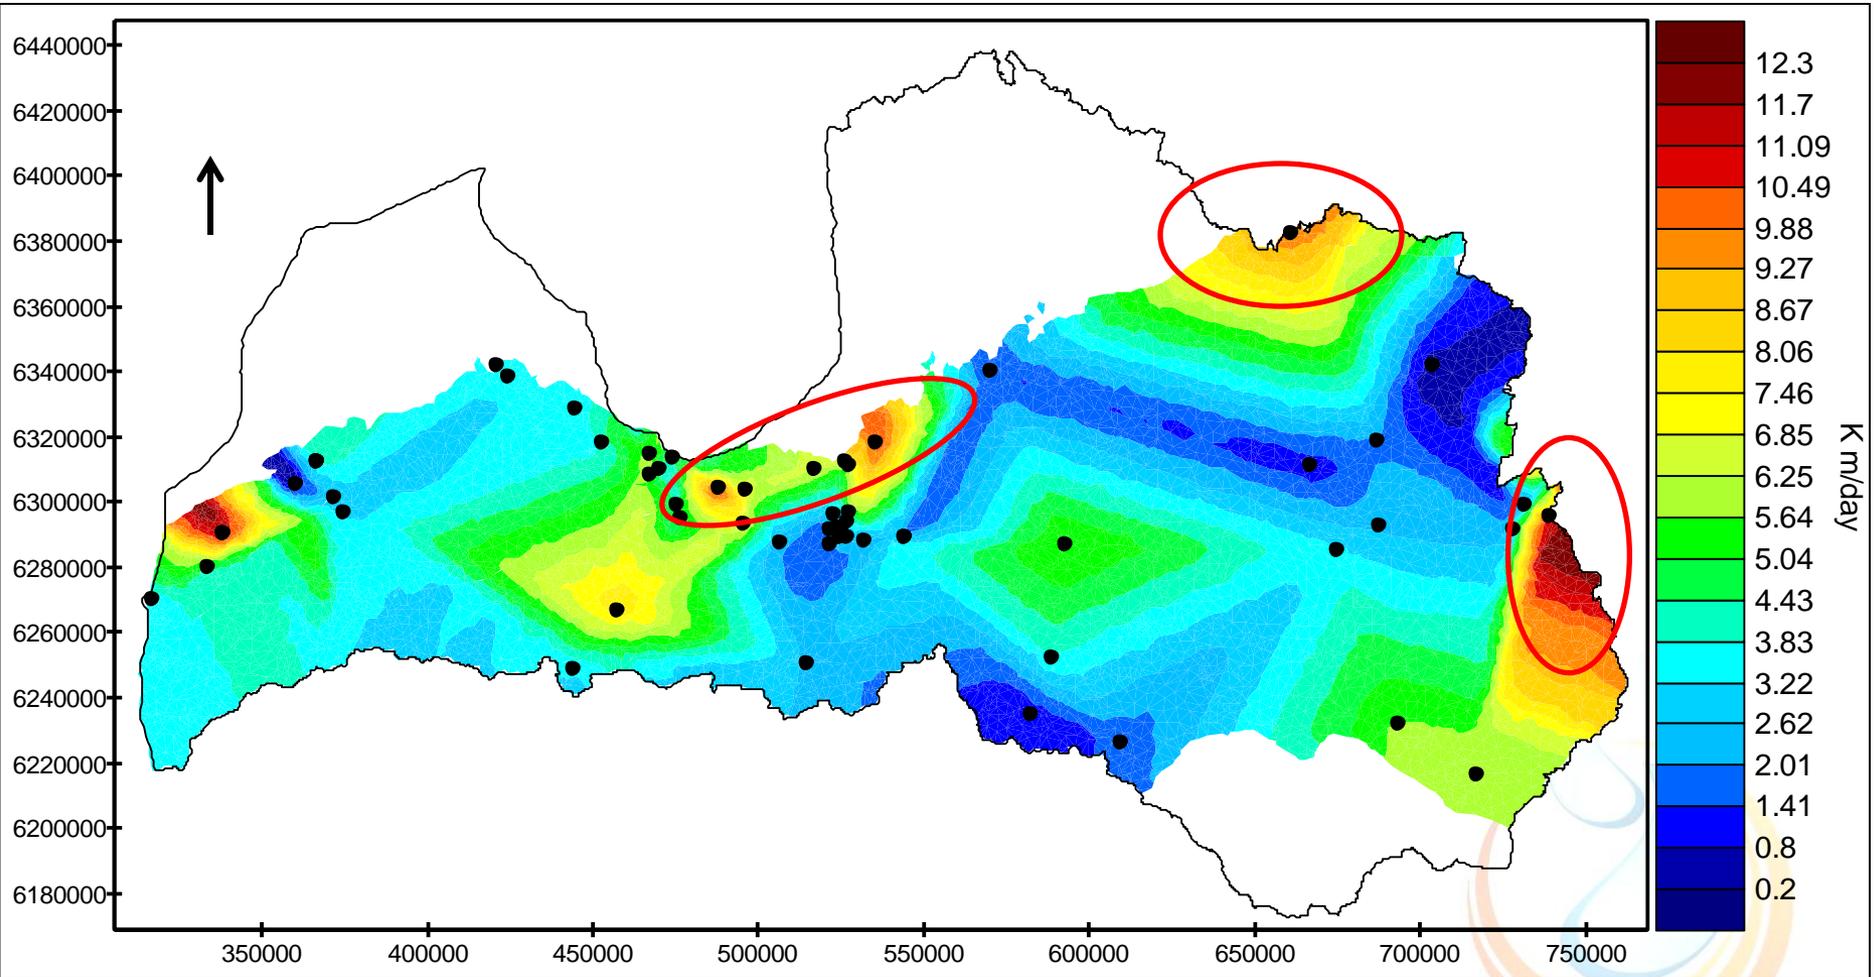

$d_{10}$  – effective diameter (mm) ;

$t$  – water temperature (°C);

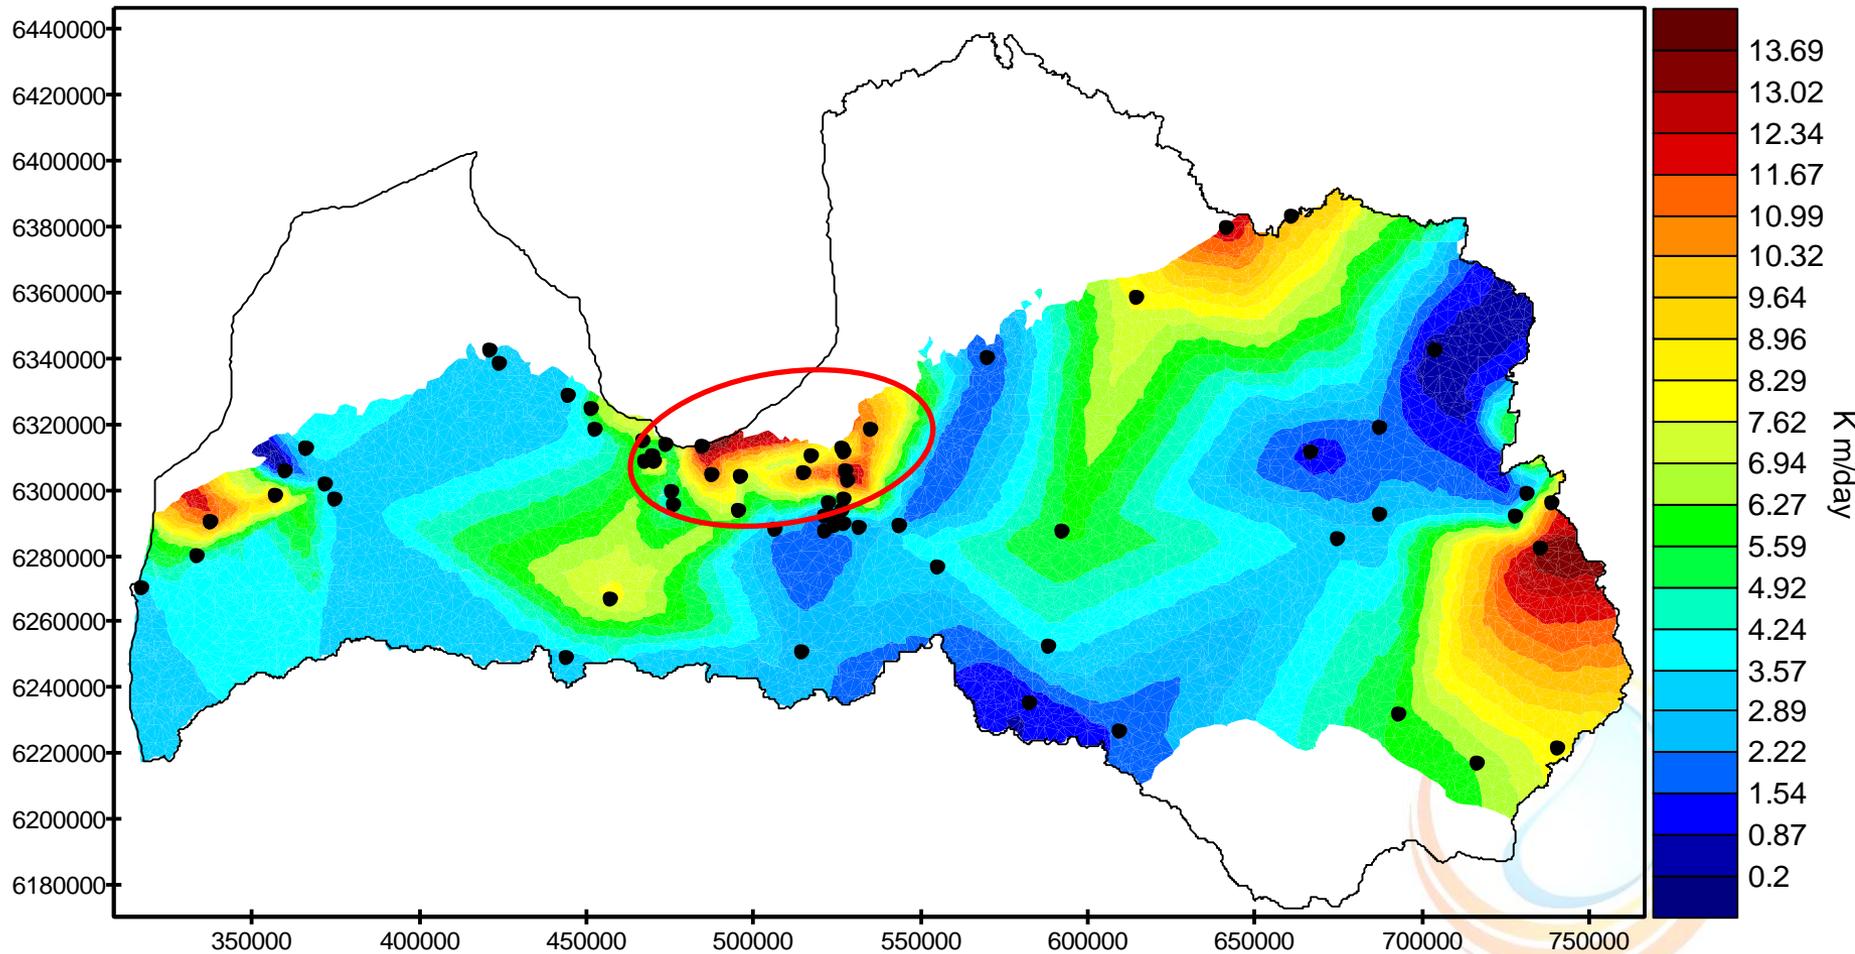

$(0,7+0,03t)$  – temperature correction (Maldivs, 1964).

# K values distribution in Rēzekne – Pērnavas aquifer provided from pumping test results and calculated values

# K values distribution in Cambrian aquifer provided from pumping test results

# Future work

## Conclusions:

- Studying hydraulic conductivity of Devonian and Cambrian clastic sediments, there exists connection between  $K$  and grain size distribution and also exists connection between  $K$  and aquifer depth – In Devonian sandstones  $K$  varies from 1 – 10 to 20 m/day, but in Cambrian aquifer from ~ 1 to 3 m/day;
- Providing researches of hydraulic conductivity in bedrock aquifers larger attention must be paid to other factors what affects hydraulic conductivity;
- Calculating hydraulic conductivity from grain size, is very important to take into account applicability of used formula and fact that changes of applicability parameters (effective diameter, uniformity coefficient, porosity, water temperature etc.) can substantially affect calculation results;

## Conclusions

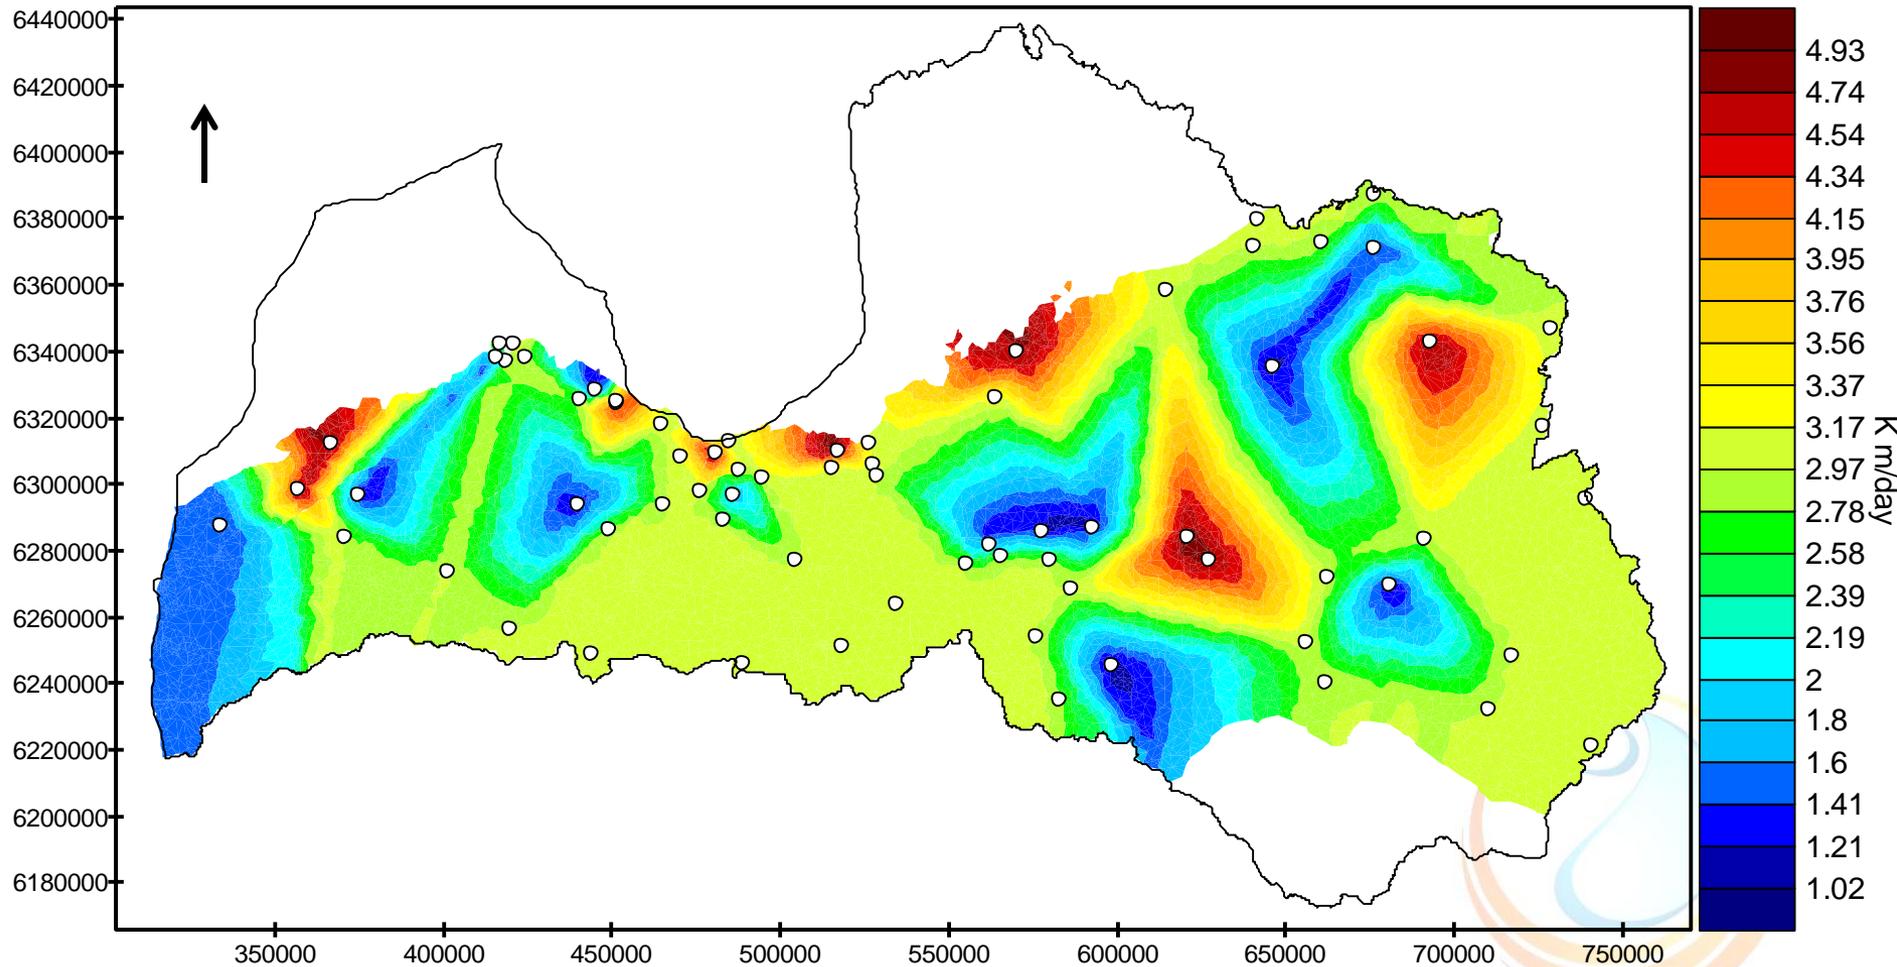

- Hydraulic conductivity values which is calculated from grain size distribution, comparing with pumping test values is different from such opinion, that calculated values characterizes only material ability to conduct water, but values which is provided by field works may characterize not only one aquifer but also aquifer below or above in case if aquitard is missing;

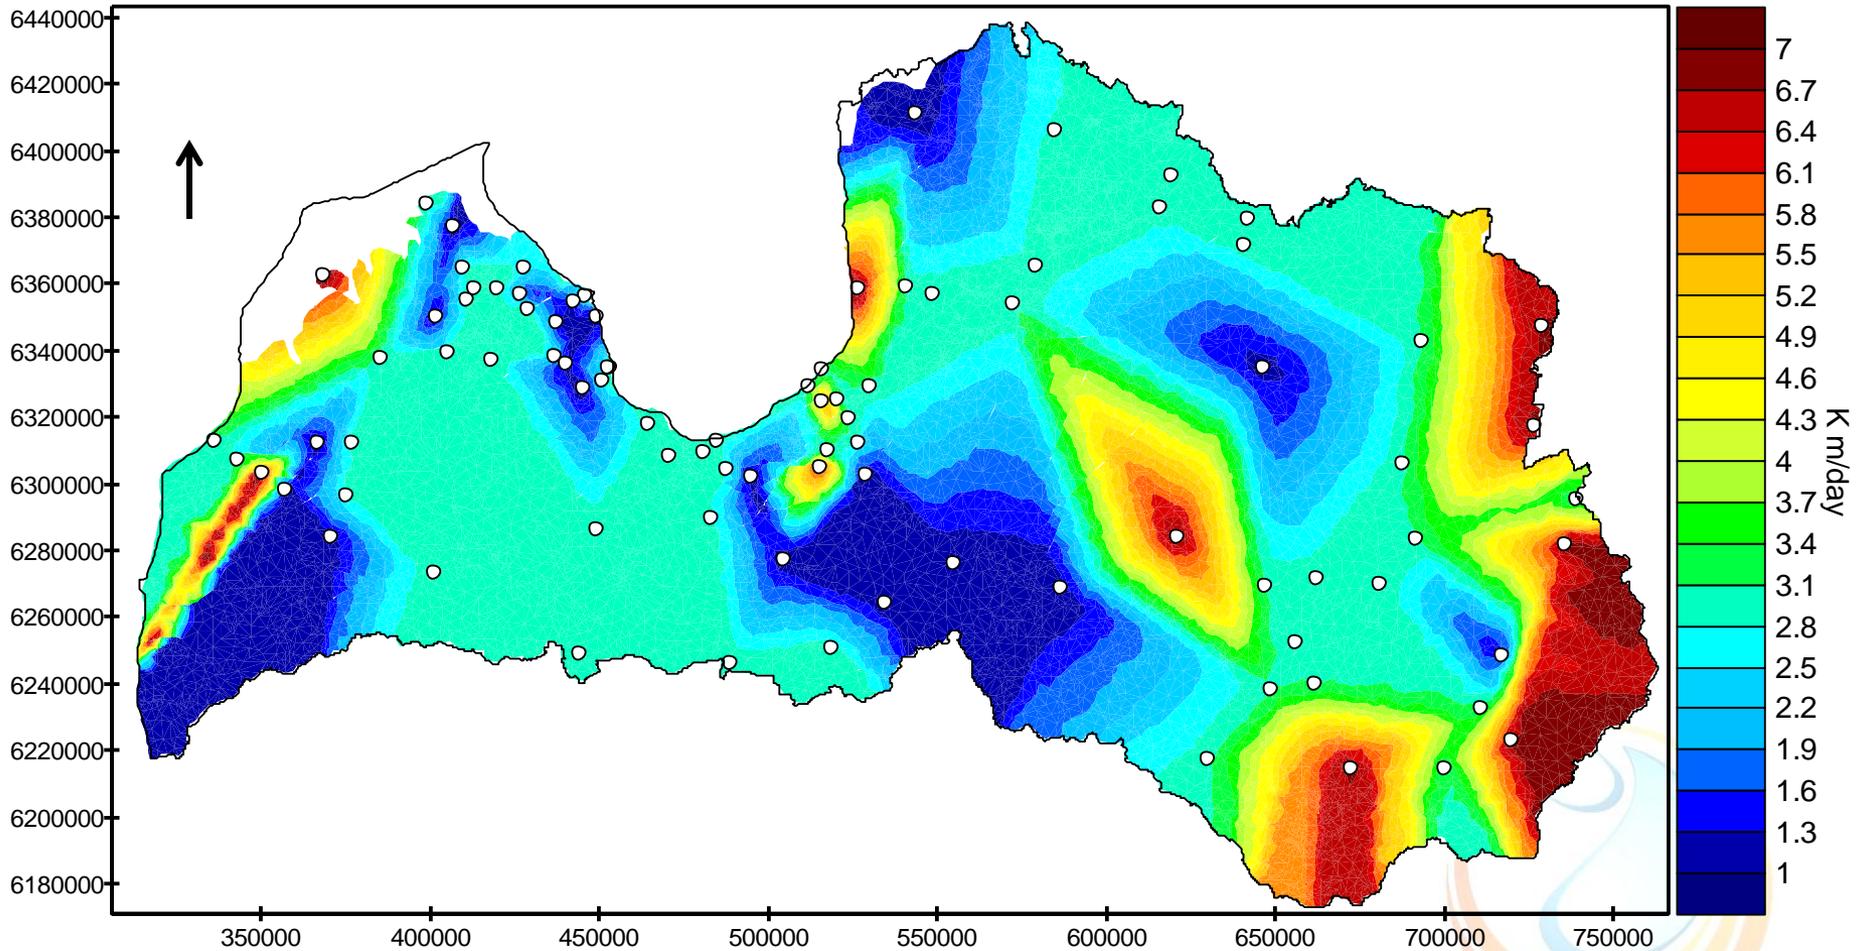

Thank you for attention!
